

Slow steps are real where the raw matrix is large, last ~50 epochs, and are not sufficient on ksd

$\frac{||W(e+1) - W(e)||}{||W(e)||}$, mean over blocks 1-7. All arms converge by epoch ~100 (AdamW norm equilibrium). The ksd scale-only arm is as slow as the committed arm and ends at random level; the arm below random is the fast one.
